Introduction

This report presents the *Official Population Projections for New York State Counties* for the period 1980-2010. The projections are done in five-year intervals over the period and data are included for each sex and five-year age groups through age 84.

The projections in this report supersede the *Preliminary Population Projections for New York State Counties* published in February 1983.

This report contains a single set of projections for each county, the 1980 Standard Metropolitan Statistical Areas, several multi-county regions, and the State of New York. Counties are arranged in alphabetical order and are followed by the SMSA's, regions and the State. The projections represent the most likely future path of population change given current trends as of 1984 and expected demographic changes through the next 25 years.

Projections Highlights

- The total population of the State is projected to increase by 7.9 percent to 18,948,273 by the year 2010,
- The number of births will peak between 1985 and 1990 at 1,267,382 for the five-year period,
- The number of deaths will increase continually between 1980 and 2010,
- By the year 2010, 15 counties will experience more deaths than births,
- The State will experience net out-migration until the 2000 to 2005 period,
- The metropolitan population of the State will increase by 7 percent between 1980 and 2010 while nonmetropolitan New York will increase by almost 16 percent,
- The population age 65 and over will increase by 36 percent by 2010 and will comprise 15.5 percent of the total population,
- The median age of the population will rise from 31.9 years in 1980 to 40.6 years in 2010,
- The proportion of the population under 15 years old will decrease from 21.2 percent in 1980 to 18.0 percent in 2010,
- The proportion of the population between the ages of 15 and 64 will be unchanged at 66.5 percent.

Methodology

The model used to project population is a demographic model known as the cohort component model. Population is projected forward by five-year age-sex cohorts utilizing individual transition rates for the three components of population change: fertility, mortality and migration.

The projections are county specific, that is, all input data are specific at the county level and each county is projected independently of other counties. The county level populations are then summed to the state, regional and SMSA total population. No attempt is made to control the county figures to a predetermined state total. These projections are for a 30-year period using the 1980 Census population as a base and are produced in five-year increments. The age-sex distribution is produced in five-year age intervals through age 84 with an open-ended category of 85 and over ending the distribution.

In addition to the components of population change, adjustments are made in selected counties to reflect the presence of large concentrations of college students, military barracks, or institutional populations. Some counties have been adjusted to reflect possible underenumeration of minorities in the 1980 Census of Population and Housing.

The development of the individual county transition rates for the components of change and the assumptions underlying the projections are discussed in more detail below.

Fertility

The absolute number of births that are projected for each county in each five-year interval is calculated by applying age-specific fertility rates to the number of women in the childbearing ages. The childbearing ages are defined as ages 15 through 49 and the fertility rates are applied to women in five year age groups within that range. The number of male and female births is determined by applying the county specific sex ratio at birth, as determined from the 1980 live births by sex reported by the New York State Department of Health, to the total number of births generated for the five-year period. The total number of births is survived using county and sex specific survivorship ratios and becomes the population age 0 to 4 at the beginning of the next projection interval.

The age-specific fertility rate is defined as the number of live births to women of a given age group divided by the total number of women in that age group. The 1980 rates were calculated by using a three-year average of county specific births (1979, 1980 and 1981) by age of mother, obtained from the

New York State Department of Health and divided by the 1980 Census population of women of childbearing ages in five-year age groups. A small number of births occur to women under the age of 15 and over the age of 49 and these births were added into the 15 to 19 and 45 to 49 age groups, respectively. These single year age-specific fertility rates are then converted to five-year rates by multiplying each rate by 5. The resulting set of rates establishes the age pattern of fertility which is unique to each county.

The age pattern of fertility for each county is projected to change over the period of 1980 to 1995 by applying the projected change in fertility for the nation as a whole to the individual county specific rates. This projected change is based upon the middle series fertility assumption used by the U.S. Bureau of the Census in the latest set of national population projections. The national projections imply some changes in the age pattern of fertility which reflect a continued delay in the mean age of childbearing. After 1995, the age pattern of fertility for each county is assumed to remain constant. This implies that future changes in fertility rates will be the same for all counties and that the differentials which existed in 1980 will continue.

Once the projected age pattern of fertility is established, the actual number of births projected in each interval is determined by the specified Total Fertility Rate (TFR). The TFR is defined as the number of children that a woman would have in her lifetime if she experienced the same age-specific fertility rates occurring in the specified year for her entire lifetime. The TFR for the 1980 to 1985 period is specified to generate an expected number of births occurring in each county. The expected number of births is based upon an extrapolation of the actual reported births for the calendar years 1980 through 1983. The Bureau of Census projects an increase in the TFR of approximately 7.1 percent to the year 1995. Between 1995 and the year 2010 the TFR for each county is projected to increase by 2.0 percent, 2.5 percent and 3.0 percent in the three five-year periods 1995 to 2000, 2000 to 2005 and 2005 to 2010, respectively. A summary of the projected Total Fertility Rates by county is given in Table 1.

Mortality

The population by age and sex is aged over time by applying age-sex specific survivorship ratios for a five-year period to the base population by five-year age group. The survivorship ratio is defined as the proportion of the initial population of a given age that will survive a five-year period and be five years older at the end of the period. The survivorship ratio is calculated from the Lx column of the life table. This column represents the number of person years lived in a particular age category by the number of people alive through the age interval. The survivorship ratios used in this set of projections differ substantially from those used in previous projections in that the life tables are, to the extent possible, county specific. In many counties with small population size (generally under 100,000) it is not possible to construct an adequate life table. County specific life tables for 1980 were developed for 26 individual counties and the remaining 36 counties were aggregated into 6 areas on the basis of population size.

The projected change in survivorship ratios by age and sex over the 30-year projection period is the same as the middle series used by the Bureau of the Census in the latest national population projections. These rates of change are based upon projections done by the Social Security Administration and assume a continued decline in mortality rates until 2005 and a slowing of the decline thereafter. Applying a single set of rates of change to the 1980 county and area specific survivorship ratios assumes that differentials that existed in 1980 will continue and that the rate of improvement in survival will be the same for all areas. This does not appear to be an unreasonable assumption since the same differentials which appear in the 1980 life tables were also apparent in the 1970 life tables. The survivorship ratios in each county or area improved between 1970 and 1980, however, there was little convergence of the rates.

Migration

The age-sex specific net migration rates used in the projections represent the results of a detailed analysis of 1970 to 1980 migration patterns for each county, as well as, a historical comparison of rates for the decades 1950 to 1960 and 1960 to 1970. The projection model generates net migrants by age and sex for each county based upon an age pattern of migration and a specified total absolute level of migration, the Crude Migration Rate.

The age pattern of migration specifies the age distribution of net migrants for each sex and is based upon the calculation of age-sex specific residual net migration for the 1970 to 1980 period. This distribution represents the propensity of one age group to migrate relative to another and for any given county tends to be stable over time. The assumption of stability in the migration pattern was tested by comparing the age patterns of migration for each county over three decades, 1950

through 1980. Though the actual Total Crude Migration Rates over the three decades differ, the age pattern of migration in most counties is stable. In those counties where the patterns changed over the three decades, the changes were primarily due to the presence of special populations, e.g., colleges, military bases or prisons. With the historical analysis as a basis, the county specific age patterns of migration are assumed to remain stable throughout the projection period for most counties. The model has the flexibility to alter the age patterns and in some counties the patterns were modified after 1985 to more accurately reflect the historical patterns.

The absolute level of net migration is measured by the Total Crude Migration Rate which is the number of net migrants over the five-year period divided by the total poplation in the initial year. The projected trend in total migration for each county reflects the five-year total net migration rates for the periods 1970 to 1975, 1975 to 1980, the three-year period 1980 to 1983 and input provided by local planning agencies throughout the review period. In most counties which experienced high rates of net out-migration during these periods, the rates were moderated through the projection period. Similarly, counties with high rates of net in-migration remained stable or were moderated. These trends are consistent with the assumption that, statewide, New York will improve in economic activity relative to the nation as a whole over the projection period. A summary of the projected Crude Migration Rates by county and sex is given in Table 2.

Special Populations

The presence of large college, military and prison populations presents special problems in the projections because of their effect on migration. These populations are concentrated in a few age groups and the change in the total special population for a county is often the result of the opening or closing of an institution. For these reasons the change in the special population is projected independently of the basic projection model. Special populations are taken account of in counties where the total of such populations is greater than one percent of the county total population.

The college population for 1980 is developed from counts of total enrollment by level and institution from the New York State Education Department. The age and sex distribution of students is estimated, using data from the Education Department's Survey of Institutions for 1977, by applying the percent distribution by age and sex in the survey data to the total Fall 1979 enrollment. These distributions are further adjusted to reflect the proportion of students who are non-migratory, i.e., attend school in their original county of residence. Projections of college enrollment by institution to 1995 were supplied by the Education Department and the percent distribution by age and sex is assumed to remain constant. After 1995 the college populations are held constant for the remainder of the projection interval.

The military population by age and sex for 1980 is estimated using data from the 1980 Census of Population and Housing. At the county level, the Census provides only a total count of military residing in group quarters. Data on the age-sex distribution for military group quarters is available at the state level and the county age-sex distribution is assumed to be the same as the state as a whole. Because of the stability of military bases the special population is held constant throughout the projection period.

Additional special adjustments were made in the counties of Jefferson, St. Lawrence and Lewis because of the U.S. Army plans to reactivate Ft. Drum. Between 1985 and 1990 there will be a transfer of approximately 27,000 military personnel and dependents to Ft. Drum. The special population adjustment in the projections account for this entire movement and was developed in consultation with local officials using the Defense Department's estimates of troop strength and dependents.

Data on the total prison population by institution, as well as, the age-sex distribution of inmates in 1980 were provided by the New York State Department of Correctional Services. This data was used directly without modification and the projected change in the inmate population is based upon the capacity of the Department's approved expansion and construction of new facilities.

Adjustments for Census Underenumeration

Counties with high proportions of minorities in 1980 are thought to be especially vulnerable to the effects of net underenumeration in certain age-sex groups. For this reason, counties which contained 10.0 percent or more of Blacks and/or persons of Spanish Origin received a positive adjustment for the effects of Census underenumeration in these groups. Selected age-sex groups were adjusted based on the estimated underenumeration as reported by the Bureau of the Census in *Current Population Reports*, Series P-23, No. 115, 1982. An assumption was made that underenumeration for persons of Spanish Origin was at least as high as

that for Blacks so the Black rates were also applied to the Spanish Origin population. No estimates of underenumeration of the Spanish Origin population are available at this point in time.

The counties in which this adjustment was made are Bronx, Erie, Kings, Monroe, New York, Queens and Westchester. The adjustment was made by adding the estimated underenumeration to the appropriate age-sex groups before projecting the 1985 population. The 1980 population is, however, the Census population as reported on Summary Tape File 2B of the 1980 Census of Population and Housing.

Sources of Data

New York State, Department of Correctional Services, unpublished tabulations of inmate characteristics, December 1980.
